

schemes are used to determine whether a module has become faulty • Fault location is used to determine

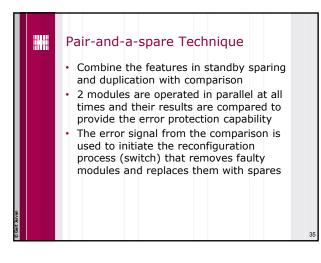

exactly which module, if any, is faulty.

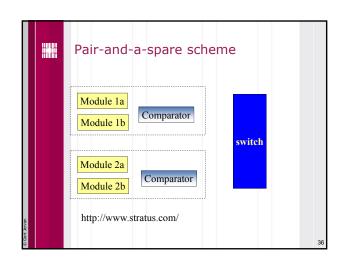

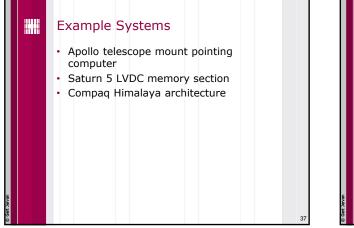

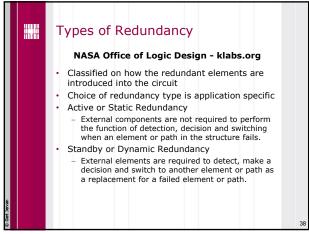

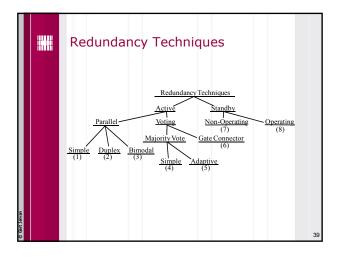

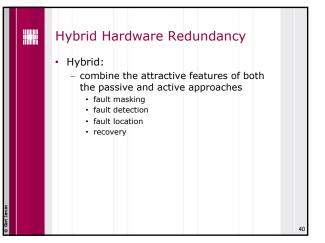

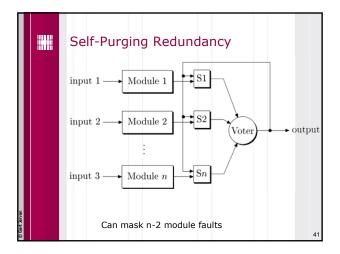

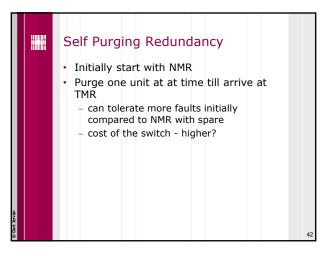

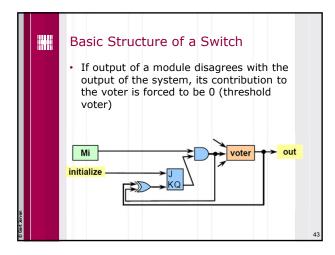

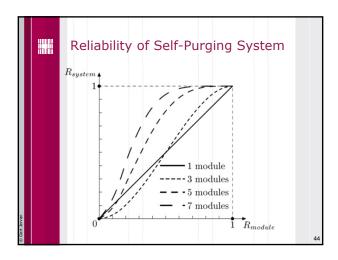

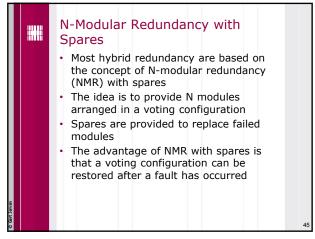

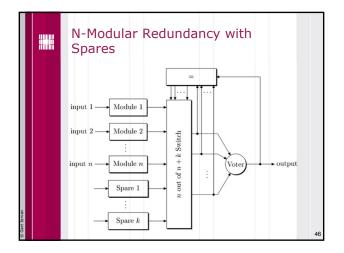

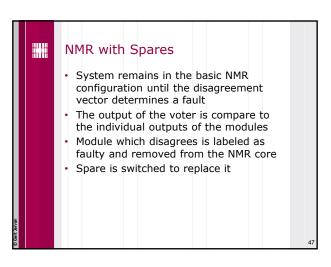

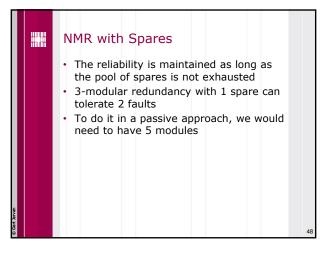

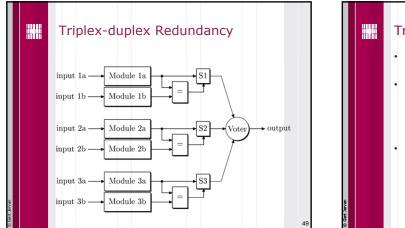

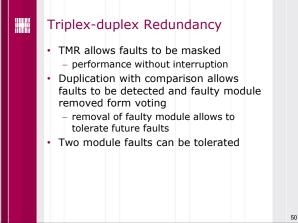

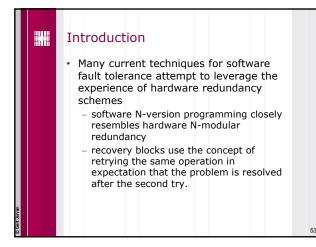

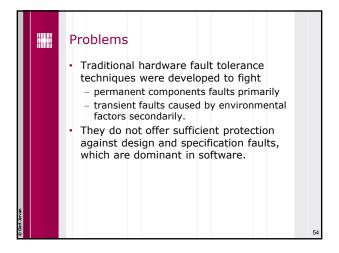

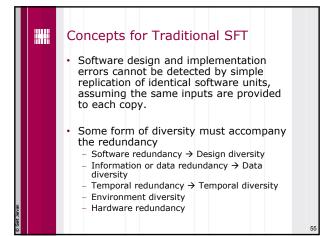

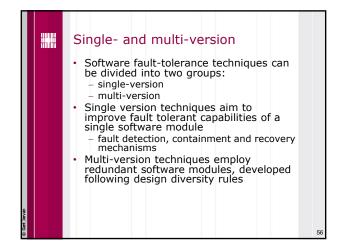

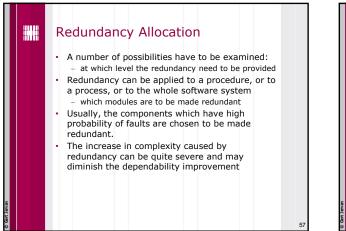

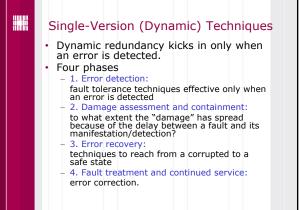

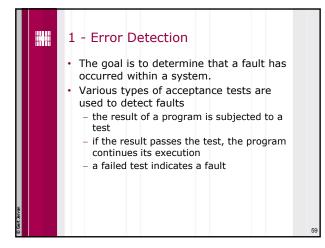

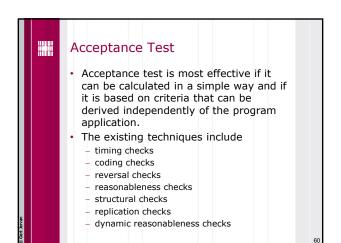

### **Timing Checks** Coding Checks • Timing checks are applicable to system Coding checks are applicable to system whose specification include timing whose data can be encoded using constrains information redundancy techniques Based on these constrains, checks are Usually used in cases when the developed to indicate a deviation from information is merely transported from the required behavior. one module to another without changing Watchdog timer is an example of a timing it content. check Arithmetic codes can be used to detect errors in arithmetic operations Watchdog timers are used to monitor the performance of a system and detect lost or locked out modules.

## Reversal Checks

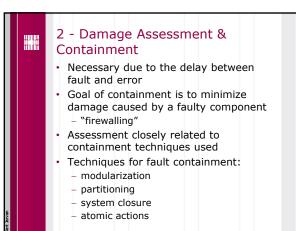

In some system, it is possible to reverse the output values and to compute the corresponding input values.

 A reversal checks compares the actual inputs of the system with the computed ones.

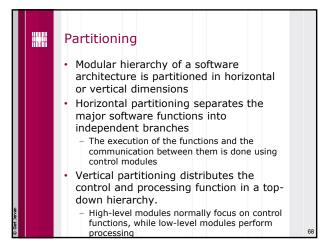

- a disagreement indicates a fault.

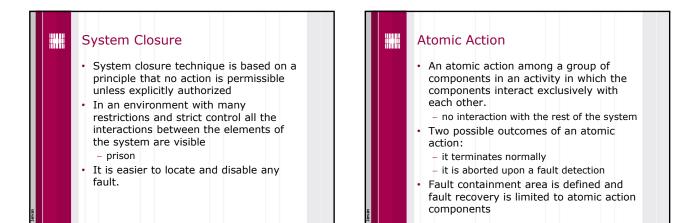

## Reasonableness Checks Reasonableness checks use semantic properties of data to detect fault. a range of data can be examined for overflow or underflow to indicate a deviation from system's requirements Maximum withdrawal sum in bank's teller machine Address generated by a computer should lie inside the range of available memory

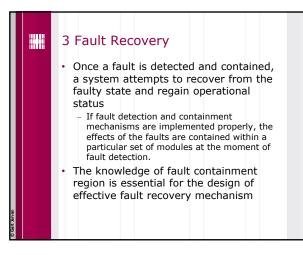

# Structural Checks Structural checks are based on known properties of data structures a number or elements in a list can be courted, or links and pointer can be verified Structural checks can be made more efficient by adding redundant data to a data structure, a ttaching counts on the number of items in a list, or adding extra pointers

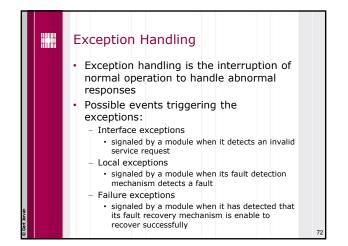

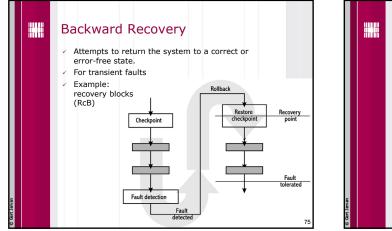

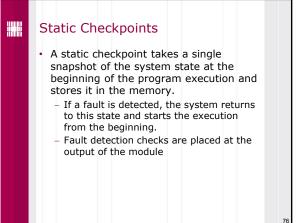

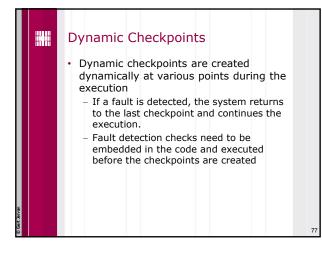

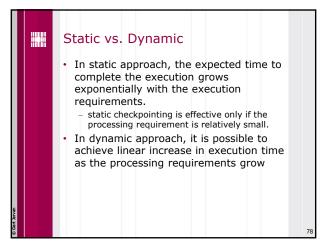

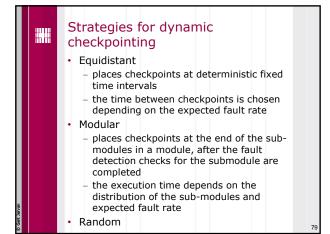

Recovery	Recovery
<ul> <li>Forward or Backward</li> <li>Forward: continues from an erroneous state by making selective corrections to the system state <ul> <li>includes making safe the controlled environment which may be hazardous or damaged because of failure</li> <li>system specific and depends upon accurate predictions</li> <li>e.g., redundant pointers in data structures, self-correcting codes</li> </ul></li></ul>	<ul> <li>Backward: relies on restoring the system to a previous safe state and executing an alternative section of the program.</li> <li>safe functionality but different algorithm</li> <li>the point to which a process is restored is called a recovery point and the act of establishing it is called checkpointing.</li> <li>BER can be used to recover from unanticipated faults including design errors.</li> <li>State restoration is not always possible in (real-time) embedded systems.</li> </ul>

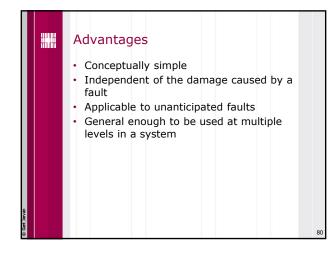

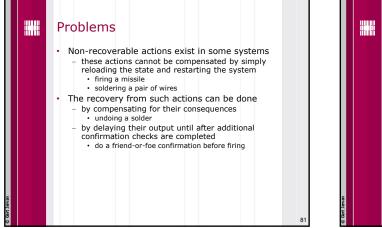

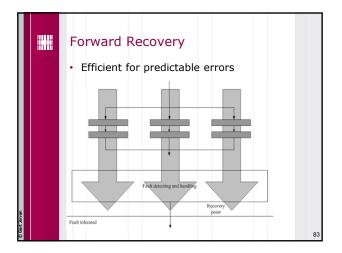

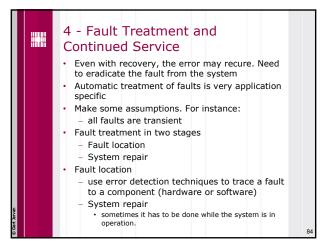

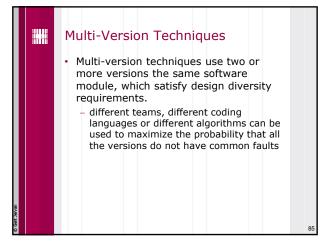

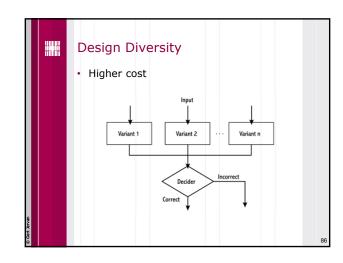

Forward Recovery
<ul> <li>Attempts to find a new state from which the system can continue operation.</li> <li>Utilize error compensation based on redundancy to select or derive the correct answer or an acceptable answer.</li> <li>Example: N-version programming (NVP), N-copy programming (NCP), and the distributed recovery block (DRB)</li> </ul>
the distributed recovery block (DRD)

# Discussion Each software fault tolerance technique need to be tailored to particular applications. This should also be based on the cost of the fault tolerance effort required by the customer. The differences between each technique provide some flexibility of application.

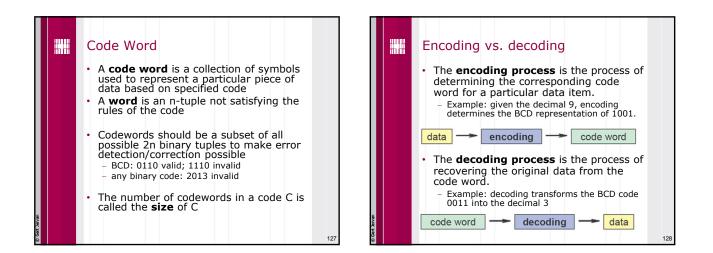

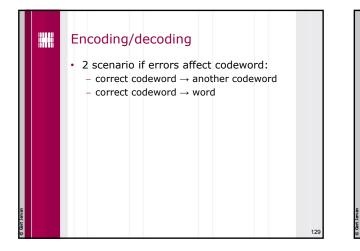

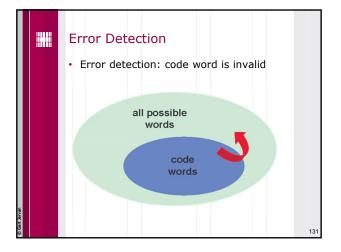

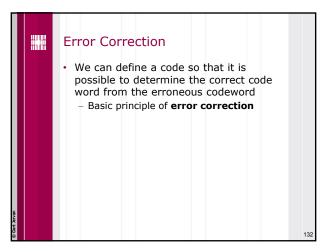

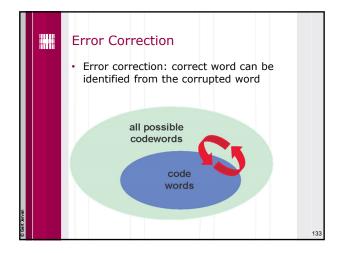

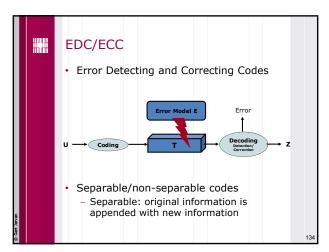

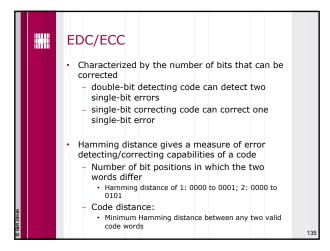

Error Detection
